Clinical Challenge

Septal perforations may arise from a variety of common conditions. One common etiology associated with septal perforation is corrective surgery for septal deviation (deviated septum).

Procedure Overview

During an evaluation by a septal repair specialist, imaging of the nasal cavity is usually obtained to determine the presence, size, and location of any septal perforations as well as any other underlying conditions that are not readily evident. Other conditions include: turbinate or adenoid hypertrophy, nasal polyps, rhinitis, chronic sinus disease, or chronic infection. It is the obligation of the surgeon to insure that all nasal disease is thoroughly evaluated. All medical conditions should be optimized prior to surgery. Once it has been determined that a patient is an appropriate candidate for septal repair, preparations are made for surgical treatment which typically include septoplasty to correct the deviated septum.

Surgical Considerations

Depending on the severity of the septal perforation and associated structural compromise of the nose (deviated septum, saddle nose deformity) a septal repair specialist may recommend concomitant reconstruction of the nose using a technique called functional rhinoplasty which aims to restore and/or improve proper breathing and reduce nasal symptoms. Functional rhinoplasty is a structural surgery, which commonly includes the use of cartilage grafts harvested from either the septal, auricular (ear), or rib cartilage of the patient. These grafts are used to structurally reinforce the nasal skeleton and may be added to the septum, tip, or dorsum of the nose.

Clinical Results

Traditional septal repair procedures carry high rates of failure. In contrast, Dr. Hamilton has pioneered his own internationally renowned techniques and holds an unprecedented 99% success rate in septal perforation repair procedures for small and large perforations of the septum.

Surgeon Comments

Dr. Hamilton- “Deviation of the septum (deviated septum) contributes negatively to support of the nose and increases the degree of symptoms experienced by patients with a septal perforation. Nasal obstruction, congestion, perforation, nosebleeds, and crusting, symptoms commonly seen with septal perforations, are common in patients with septal deviation alone. When a deviated septum and septal perforation are present simultaneously in the same patient, symptoms grow exponentially. A successful outcome for these patients always requires concomitant repair of the deviated septum and septal perforation.”
Dr. Jason Hamilton is the Director of Plastic and Reconstructive Surgery for the Osborne Head and Neck Institute, is double board certified by the American Board of Facial Plastic and Reconstructive Surgery and the American Board of Otolaryngology/Head and Neck Surgery, and is one of only handful of septal perforation specialist worldwide.
